

Exploratory Data Analysis

Mental Health

Anxiety Levels: Percentage Distribution

Depression Levels: Percentage Distribution

- The pie charts illustrate the distribution of **anxiety and depression levels** among the surveyed population of widows. The anxiety chart reveals that a significant proportion (**approximately 62%**) **experience moderate to severe anxiety**, while a smaller percentage (**around 38%**) **report minimal anxiety**.
- The depression chart shows that **60% reported minimal depression**, which may also indicate an **underestimation of depressive symptoms**.

Suicidal Thoughts Level Distribution

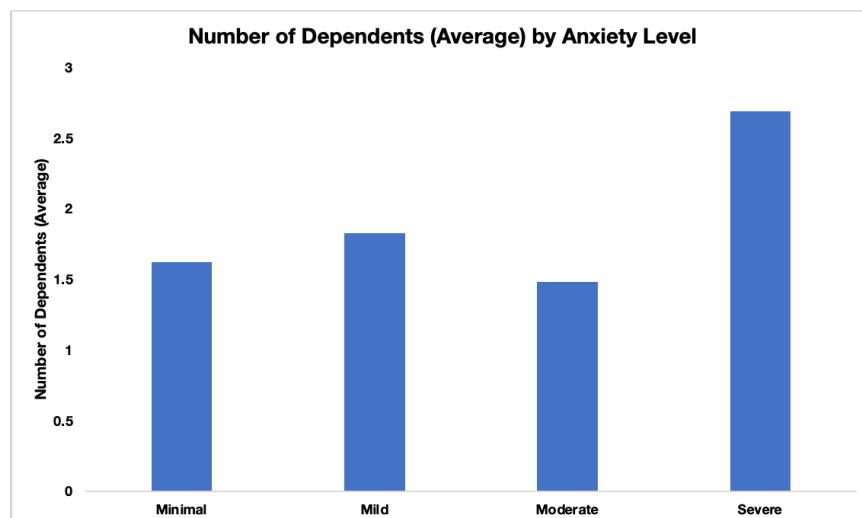

- The bar chart on Suicidal Thoughts Level Distribution shows that most of the surveyed population (**425 individuals**) reported **"Not at all"** when asked about the **frequency of suicidal thoughts**.

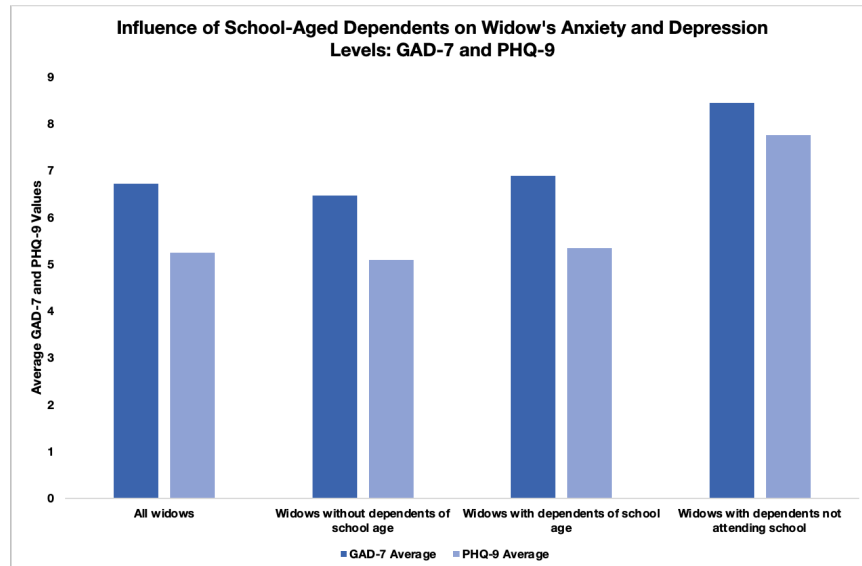

- This scatter plot illustrates the **relationship between PHQ-9 scores (indicating depression severity) and GAD-7 scores (indicating anxiety severity)** in a population.
- The data points show a general trend of **increasing PHQ-9 scores (depression) as GAD-7 scores (anxiety) increase**. This suggests a **moderate positive correlation (0.61)** between anxiety and depression levels in this population, indicating that individuals with **higher anxiety levels** also tend to have **higher levels of depression**.

Number of Dependents and Anxiety/Depression Levels

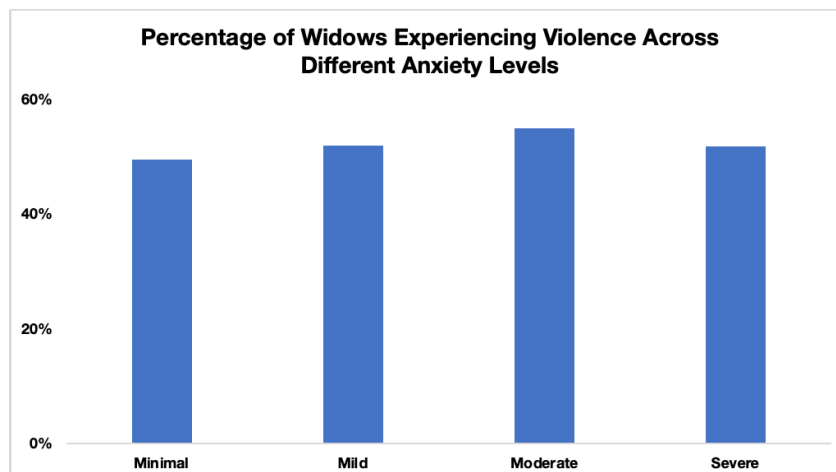

- The bar chart illustrates a **potential relationship between anxiety levels and the average number of dependents**. The chart shows that as the **level of anxiety increases**, so does the **average number of dependents**.
- This suggests that individuals experiencing **higher levels of anxiety** may be more likely to have a **greater number of people relying on them for support**. This could be due to various factors such as family responsibilities, caregiving roles, or financial obligations.

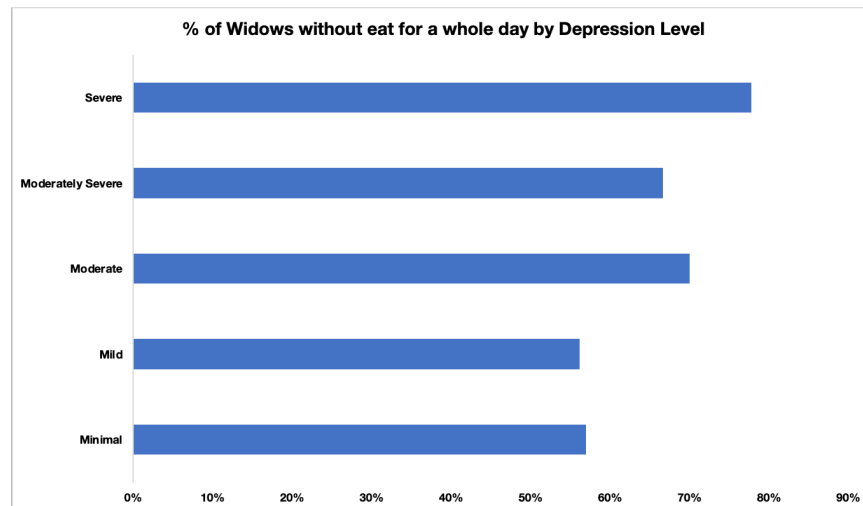

- **Widows with school-aged dependents have significantly higher average GAD-7 and PHQ-9 scores**, indicating increased anxiety and depression compared to widows without school-aged dependents.
- **Widows with dependents not attending school exhibit the highest levels of anxiety and depression**, suggesting additional stressors associated with caring for dependents outside of a structured school environment.

Violence and Anxiety

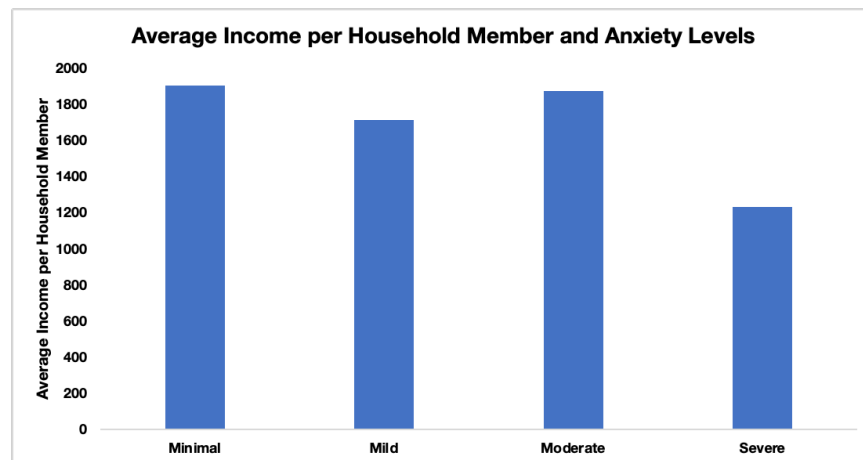

- The bar chart initially **appears to show an increasing trend in the percentage of violence in widows from Minimal to Moderate anxiety levels**. However, **this trend does not continue with Severe anxiety**, suggesting that the **relationship between anxiety level and violence experience is not linear**.
- This unexpected pattern could be due to several factors. For example, **severe anxiety might lead to increased isolation and reduced social interaction**, potentially limiting exposure to situations of violence.
- Approximately **51% of the widows reported experiencing violence** related to widowhood.

Nutrition and Depression

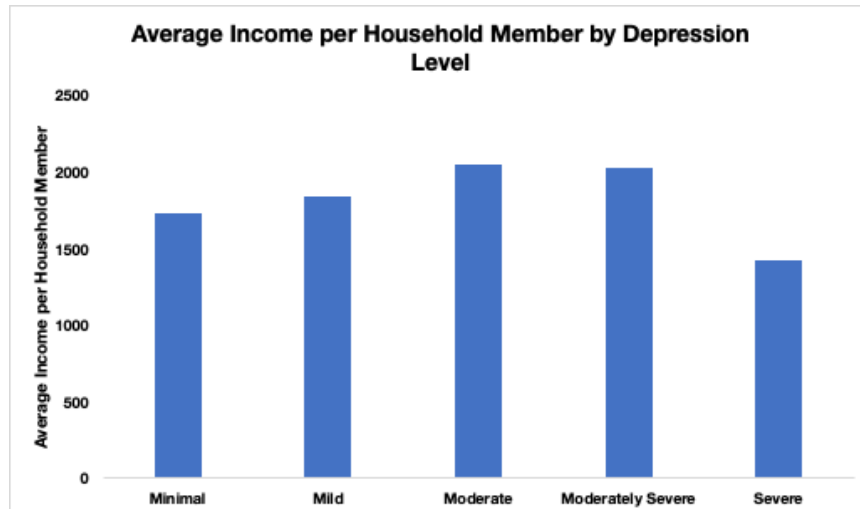

- The chart shows a **clear trend where the percentage of widows going without food for a whole day increases as the severity of depression increases**. This suggests a **strong association between the severity of depressive symptoms and the likelihood of experiencing food insecurity**.
- The percentage of **widows experiencing a full day without food is significantly higher in the "Severe Depression" group compared to the "Minimal Depression" group**, highlighting the **potential impact of severe depressive symptoms on basic needs like food access**.

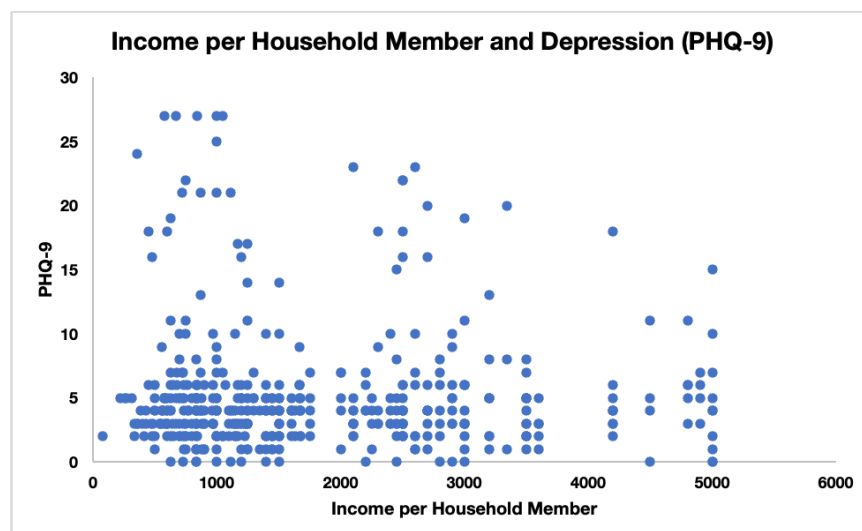

Income and Anxiety/Depression Levels

- The chart suggests a **potential relationship between anxiety levels and average income per household member**. Individuals with **minimal and moderate anxiety levels appear to have higher average incomes per household member compared to those with mild and severe anxiety**.
- The **"Average Income per Household Member"** in this chart was calculated by **dividing the total household income by the number of dependents plus the widow herself**.

- The chart indicates a **potential negative relationship between depression levels and average income per household member**. Individuals with **severe depression** tend to have **lower average incomes** compared to other levels of depression.

- There is **no significant overall correlation between income per household member and PHQ-9 scores**.
- However, the **correlation becomes stronger (-0.28 for moderate to severe depression and -0.41 for severe depression)** when the analysis is restricted to widows with **moderate to severe depression and severe depression**, suggesting a **moderate negative correlation between low income and higher depression severity** within this subgroup.

Conclusions

- The analysis of the mental health and socio-economic factors affecting widows highlights critical relationships and insights. **Anxiety and depression levels** exhibit a **moderate positive correlation (0.61)**, suggesting that individuals with high anxiety are also more likely to experience depression. **Socio-economic stressors**, such as food insecurity and the number of dependents, **strongly influence mental health outcomes**. For example, **widows with severe depression**

report significantly higher instances of going without food for an entire day, and those with severe anxiety tend to support a greater number of dependents.

- An important discovery is the **relationship between income per household member and PHQ-9 scores**, particularly among **widows with moderate to severe depression**. While no significant overall correlation exists, a **stronger negative correlation (-0.28 to -0.41)** emerges within this subgroup. This finding indicates that **lower income per household member is moderately associated with higher depression severity**, emphasizing the **compounded effects of financial stress on mental health**.
- The analysis suggests that **correlations between socio-economic factors and mental health outcomes become stronger at higher levels of anxiety and depression**. This trend highlights the escalating **impact of financial and social stressors as mental health challenges intensify**, further underscoring the **importance of targeted, multi-faceted interventions**.
- **Widows with school-aged dependents** exhibit significantly **elevated GAD-7 and PHQ-9 scores**, indicating **higher levels of anxiety and depression** compared to widows without such dependents. This disparity is **particularly pronounced for widows with dependents not attending school**, suggesting that the **absence of a structured school environment may add further strain and contribute to increased mental health challenges**.
